

Features Request 07-07 — Response

All eight items are addressed in **v3.0.10-preview**. Two turned out to be deeper product bugs than they looked — the details are below, item by item, in your original order.

1. Condition for Ticket Source

DONE — new workflow condition

Workflows can now route on how a ticket arrived: **Email, Portal, Phone, Chat, API, Webhook, or Agent-created** — across both origins. FreshService tickets keep their own source codes; Ticket Pulse-born tickets now record their channel at creation (app → Agent, inbound mailbox → Email, public API → API), and existing tickets were backfilled. Portal and Webhook values are reserved and ready for the intake channels you're envisioning — when those land, the condition works with no further changes. Find it in the condition builder as "Ticket source".

2. Internal note composer: hide Templates, show Quick notes

DONE

In Internal-note mode the composer now offers **Quick notes only**. Reply templates are requester-facing content and stay available in Reply and Forward modes.

3. No button to create a workflow / sub-workflow; trigger not editable

DONE — all three

There's now a primary **"New workflow"** button: name it, pick a trigger from a plain-language grouped picker, or start from the template gallery (folded into the same dialog). Choosing **"Sub-workflow (on demand)"** creates a workflow that never fires on its own — it runs only when another workflow calls it, and the Run-workflow step lists sub-workflows first. The **trigger is now editable** in the inspector: your steps are kept, the graph is re-validated, and a live workflow pauses until you re-publish it on the new event. (Each trigger group header also has a "+" to create directly into that trigger.)

4. AI first-reply draft — is it actually working?

FIXED — it was real, but it could never run

Excellent catch. The template's machinery (LLM draft → staged proposal → approve/edit/dismiss card) was fully implemented — but a deep audit found it could **never fire**, for two stacked reasons: (1) after-hours routing silently suppressed every standard ticket-created workflow at night, email or not; (2) variant routing suppressed installed templates whenever a default workflow existed. Both are fixed: automation that sends no email now runs around the clock, and installed templates run alongside your default workflows. A scripted end-to-end audit now passes 16/16 (draft staged with confidence, approve-and-send goes through the real reply path, dismiss clears). Discoverability: templates now live in the "New workflow" dialog, and tickets with a waiting draft show a **Draft chip on the queue**. One behavior to know: tickets created with "Notify requester" off intentionally skip all workflows (silent creation).

5. “Stage for approval” — Notification workflow definition is invalid

FIXED — plus honest error messages

Two problems. The rule: “Stage for approval” only accepted an LLM step before it — staging a **templated** reply is now supported too (Template → Stage for approval publishes fine; the card labels it “Workflow-drafted reply”). The experience: the save error now lists the **specific** validation problems instead of the generic line, and the editor flags an invalid arrangement before you even save. We also found and fixed a validator drift that blocked publishing any workflow without a send-email step from the UI.

6. Linking a ticket: “Both tickets must exist in this workspace”

FIXED

The link box wanted an internal database id — you were typing what the UI shows. Linking, mark-as-duplicate and merge now accept **TP-1042**, **#231164**, or a **bare number** (workspace-scoped), the placeholder says so, suggestion chips fill the visible reference, and a miss names the reference it couldn't find.

7. Remove Time Tracking

DONE

The Time-tracked card and its API are gone. Historical entries remain readable in each ticket's activity trail; no data was destroyed.

8. Workflow page overhaul

DONE — incremental redesign, foundation for more

The list is now a proper index: search-as-you-type, Enabled/Failing filters, an **inline on/off toggle** on every row, last-run health with relative times, and a pinned “needs attention” strip when something is failing. The “Add step” palette is grouped (Logic & flow / Email / Ticket actions / Integrations) with one-line explanations, and the canvas nodes got clearer selected/hover states. We reviewed the ecosystem per your ask: the canvas already runs on **React Flow** — the same library Stripe and Typeform build on — so the redesign focused on the layers around it. A deeper editor re-architecture (full-screen editor route) is scoped as a follow-up if you want it.

Verification

Backend 710/711 tests (the one failure is a known pre-existing case outside this scope), frontend 69/69, lint clean on both. Two scripted dev self-tests: the wrap suite 10/10 and the AI first-reply audit 16/16. Detailed test steps: docs/QA_Test_Plan_v3.0.10.docx.
